Abstract—NTC thermistors of Y-Al-Mn-Fe-Ni-Cr-O systems were fabricated by using normal ceramic processing for wide temperature range measurement. Pt-Rh alloy as electrodes was inserted into the body during the forming process to increase the reliability of high temperature and to decrease the contact resistance. The properties were analyzed by XRD, SEM and resistance measurement. There are no distinct XRD patterns between Y_{0.2}Al_{0.1}Mn_{0.2}Fe_{0.16}Ni_{0.12}O_3 and Y_{0.2}Al_{0.1}Mn_{0.26}Fe_{0.16}Ni_{0.26}Cr_{0.01}O_3 because of too small content of Cr_{2}O_3 as a dopant, to make peak difference or new phases within the XRD resolution. SEM images and resistance behaviors show the different properties. With the addition of Cr_{2}O_3 as a dopant, the crystallinity and the grain size were decreased and increased, respectively. The resistance behaviors were similar but the values are low with Cr_{2}O_3. The specimens show the straight line relationship between the electrical resistivity and the temperature over a wide temperature range, indicating NTC thermistor characteristics.

Keywords—NTC thermistor; microstructure; wide temperature range; electrical resistance

I. INTRODUCTION

Negative temperature coefficient (NTC) thermistors are thermally sensitive resistors whose resistance decreases with increasing temperature [1-4]. They are mainly used in electronics for the suppression of in-rush current, for temperature measurement and control, and for compensation for other circuit elements [5-6].

The measurement range from low- to high-temperature is entirely insufficient for common ceramic thermistors because the coefficient of temperature sensitivity (or B constant) is usually high, over 4500K. Thus, the thermistors are classified by the room temperature applications below 100°C and the medium temperature applications between 100 °C and 300 °C. Especially in the application of automobile and spaceship, it is necessary to measure a wide range from room temperature to very high temperature. Thermistors for these applications have to the value of hundreds of kΩ at room temperature and several decades of Ω at 900 °C. To purpose these goals, the researchers have to focus to find a materials which has the low B constant, the linearity in the wide temperature range and the stable property and phase at high temperature.

Previously, the researches on NTC thermistors were predominantly focused on spinel or spinel-like structure. Those most used in practice are based on solid solutions of transition metal oxides, such as MnO_x, CoO_y, and NiO, with the general formula AB_2O_3. However, their application is commonly limited to temperatures below 200 °C [7-12]. Feltz and Polzl have proposed a system of compositions Fe_{1-x}Ni_{x}O_{3-δ} based on the spinel structure for high temperature applications [13]. Yet B constants are not stable for temperatures below 400 °C, which limits the temperature range for applications. In the special application, ZrO_2 and Y_{2}O_3 thermistor could be used only at high temperature above 500 °C because of too high resistance below 300 °C.

Oxide ceramic semiconductors based on the perovskite type structure are expected to be more available to measure wide temperature range from low- to high-temperature [14-15]. Relatively high conductivity values and low activation energies or even metallic behavior are often found for perovskites. PTC ceramics based on acceptor doping, e.g. by substitution of Fe^{3+} for Ti^{4+} in the composition of SrTi_1-xFe_xO_3 perovskite structure provide a low or zero B constant over 550 °C [16-18]. LaCoO_3 has a room-temperature conductivity with metallic behavior above 330 °C [19-20].

Y_{2}O_3 and Al_2O_3 are well known refractory material and have high resistance at high temperature. The transition metal oxides like MnO_2, Fe_2O_3, NiO and Cr_2O_3 are known the composition for room temperature thermistor. Thus, it could be possible to establish a wide range thermistor by the mixture of transition metal oxides and refractory material like Al_2O_3 and Y_2O_3. It is thus required to expand the selection of suitable composition with the desired electrical properties for wide temperature range measurement. In the present study, the microstructure and electrical properties of Y-Al-Mn-Fe-Ni-Cr-O system were studied on NTC thermistor for wide temperature applications.

II. EXPERIMENTS

Y_{2}O_3, Al_2O_3, MnO_2, Fe_2O_3, NiO, and Cr_2O_3 powders with high-purity (≥ 99.5%) were used as the chemical reagents to establish a wide range thermistors. These powders were weighed for the composition of Y_{0.2}Al_{0.1}Mn_{0.27}Fe_{0.16}Ni_{0.12}O_3 and Y_{0.2}Al_{0.1}Mn_{0.26}Fe_{0.16}Ni_{0.26}Cr_{0.012}O_3.
The wet-blending was performed by ball-milling of the mixtures of weighed powders for 12 h. The wet-blended mixtures were dried at 120 °C for 24 h. The mixture was subsequently calcined at 1200 °C with a heating rate of 5 °C/min for dwell time of 2 h.

The sintered mass was again crushed and pulverized to obtain the fine powder. Subsequently, the fine powders were pressed at 120 MPa into rectangular mold. The size of green pellets is 2 mm x 1.5 mm x 2 mm and it has a pair of inserted Pt-Rh (13%) wires as electrodes as shown in Fig. 1. The diameter of Pt-Rh electrode is 0.30 mm. The distance between 2 wires and the inserting depth into the pellet are 1 mm.

The pellets were co-sintered, ceramic body and Pt-Rh metals, at 1400°C for 1 h in air atmosphere. The crystal structure of the as-sintered specimens was analyzed with X-ray diffraction (XRD) (Rigaku DMAX 2500) using Cu Kα (0.15406 nm) radiation at 40 kV and 25 mA. The XRD patterns were obtained over the range of 10 ~ 70° 2θ. The changes in microstructures of the as-sintered specimens were investigated by using a field emission scanning electron microscope (FESEM; Hitachi S-4700). The electrical resistance as a function of temperature for the as-sintered specimens was measured by using a digital multi-meter (hp34401B).

### III. Results and Discussion

The XRD patterns of Y₀.₂Al₀.₁Mn₀.₆₄Fe₀.₁₆Ni₀.₂₇Oₓ with or without 0.012mol Cr₂O₃ as a dopant were shown in Figure 2. The new phases were formed after sintering at 1400 °C for 1 h. Compared to the each unit powder after sintering, the similar XRD peaks were detected and it is known the perovskite phase and others. There are no peak differences between them because the amount of Cr₂O₃ is too small to make peak differences or new phases within the XRD resolution.

The SEM images obtained from the cross section of Y₀.₂Al₀.₁Mn₀.₆₄Fe₀.₁₆Ni₀.₂₇Oₓ and Y₀.₂Al₀.₁Mn₀.₂₆₄Fe₀.₁₆Ni₀.₂₆₄Cr₀.₀₁₂Oₓ were shown in Fig. 3. Although it is difficult to find a difference of XRD peaks as shown Figure 2, the SEM image clearly different from the addition of small content of 0.01mol Cr₂O₃. The SEM image shows a sharp crystal plane in the case of non doped Cr₂O₃. Y₀.₂Al₀.₁Mn₀.₆₄Fe₀.₁₆Ni₀.₂₇Oₓ. However, it is difficult to find a sharp crystal plane for Y₀.₂Al₀.₁Mn₀.₂₆₄Fe₀.₁₆Ni₀.₂₆₄Cr₀.₀₁₂Oₓ with the dopant of 0.013mol Cr₂O₃. The grain sizes of non doped Cr₂O₃ as shown in Figure 3(a) is smaller than those of doped Cr₂O₃ as shown in Figure 3(b).

Figure 2. The XRD patterns of (a) Y₀.₂Al₀.₁Mn₀.₆₄Fe₀.₁₆Ni₀.₂₇Oₓ and (b) Y₀.₂Al₀.₁Mn₀.₂₆₄Fe₀.₁₆Ni₀.₂₆₄Cr₀.₀₁₂Oₓ.

Figure 3. SEM images of cross section of (a) Y₀.₂Al₀.₁Mn₀.₂₇-Fe₀.₁₆Ni₀.₂₇Oₓ and (b) Y₀.₂Al₀.₁Mn₀.₂₆₄Fe₀.₁₆Ni₀.₂₆₄Cr₀.₀₁₂Oₓ.
The microstructures without pores grain boundaries or within grains show the best sintering effect for high densification to each.

Fig. 4 shows plots of the resistance against the reciprocal of the absolute temperature (1/T) for the system Y-Al-Mn-Fe-Ni-O NTC thermistors with or without Cr$_2$O$_3$ content. The resistance decreases exponentially with temperature. It is found that the NTC thermistors operate steadily with the straight line relationship between the electrical resistance and the temperature over a wide temperature range, indicating NTC thermistor characteristics.

The slope of resistivity versus 1/T curve is taken generally as a measure of the activation energy of conductivity. In the case of thermistor, the slope of resistance versus 1/T is the B constant, sometimes called the called the coefficient of temperature sensitivity.

$$B_{T_1/T_2} = \ln\left(\frac{R_1}{R_2}\right) / T_1 - 1 / T_2$$

Where $R_1$ and $R_2$ are the resistances measured at the absolute temperature of $T_1$ and $T_2$, respectively.

The B constant between 0°C and 600°C is 3636K for Y$_{0.2}$Al$_{0.1}$Mn$_{0.2}$Fe$_{0.16}$Ni$_{0.27}$O$_x$ and 3876K for Y$_{0.2}$Al$_{0.1}$Mn$_{0.264}$Fe$_{0.16}$Ni$_{0.27}$Cr$_{0.012}$O$_x$. The resistance at 0°C and 600°C is measured 100kΩ and 9 Ω for Y$_{0.2}$Al$_{0.1}$Mn$_{0.27}$Fe$_{0.16}$Ni$_{0.27}$O$_x$ and 300kΩ and 12 Ω for Y$_{0.2}$Al$_{0.1}$Mn$_{0.27}$Fe$_{0.16}$Ni$_{0.27}$Cr$_{0.012}$O$_x$, respectively. The mixture of refractory oxides and transition metal oxides extend the measure range from 0°C to 600°C and the addition of Cr$_2$O$_3$ increase the resistance and the B constant.

These phenomena could be explained to the change of microstructure and activation energy of conduction carriers. Generally, the resistance is increased with the size decrement of grains for a sintered ceramics because the grain boundaries could be the scattering centers of the conduction carriers. The grain size and the total length of grain boundaries for a sintered ceramics are in inverse proportion to each other, as shown in Figure 3. Although the grain sizes of Y$_{0.2}$Al$_{0.1}$Mn$_{0.26}$Fe$_{0.16}$Ni$_{0.27}$Cr$_{0.012}$O$_x$ are bigger than those of Y$_{0.2}$Al$_{0.1}$Mn$_{0.27}$Fe$_{0.16}$Ni$_{0.27}$O$_x$, the resistance of the former is high. It means that the resistance difference could not relate to the scattering effect at the grain boundaries for the conduction carriers.

The reason for the dependence of the B constant on these Y-Al-Mn-Fe-Ni-Cr-O systems is not still clear at present. To elucidate the properties of the B constant and the electrical behaviors, further investigation will be necessary, i.e., exact carrier type and concentration, the analysis of micro- and crystal-structure, and the consideration of defect chemistry and structure of the samples.

The further analyses for the difference of the electrical resistance and the B constant will be reported at the conference.

IV. CONCLUSION

The mixtures of refractory oxides like Y$_2$O$_3$, Al$_2$O$_3$, and transition metal oxides like MnO$_2$, Fe$_3$O$_4$, NiO, and Cr$_2$O$_3$ powders were prepared by normal ceramic processing for the composition of Y$_{0.2}$Al$_{0.1}$Mn$_{0.2}$Fe$_{0.16}$Ni$_{0.27}$O$_x$ and Y$_{0.2}$Al$_{0.1}$Mn$_{0.264}$Fe$_{0.16}$Ni$_{0.27}$Cr$_{0.012}$O$_x$. The sintered specimens have high densification and good properties of NTC thermistors. With the addition of Cr$_2$O$_3$ as a dopant, the crystallinity and the grain size were decreased and increased, respectively. The resistance decreases exponentially with temperature. The specimens show the straight line relationship between the electrical resistance and the temperature over a wide temperature range, indicating NTC thermistor characteristics. Additionally, these systems extend the measurement range of NTC thermistor from 0°C to 600°C.
