RATIO-TO-REGRESSION ESTIMATOR IN SUCCESSIVE SAMPLING USING ONE AUXILIARY VARIABLE

Zoramthanga Ralte\textsuperscript{1}, Gitasree Das\textsuperscript{2}

ABSTRACT

The problem of estimation of finite population mean on the current occasion based on the samples selected over two occasions has been considered. In this paper, first a chain ratio-to-regression estimator was proposed to estimate the population mean on the current occasion in two-occasion successive (rotation) sampling using only the matched part and one auxiliary variable, which is available in both the occasions. The bias and mean square error of the proposed estimator is obtained. We proposed another estimator, which is a linear combination of the means of the matched and unmatched portion of the sample on the second occasion. The bias and mean square error of this combined estimator is also obtained. The optimum mean square error of this combined estimator was compared with (i) the optimum mean square error of the estimator proposed by Singh (2005) (ii) mean per unit estimator and (iii) combined estimator suggested by Cochran (1977) when no auxiliary information is used on any occasion. Comparisons are made both analytically as well as empirically by using real life data.

Key words: ratio-to-regression estimator, auxiliary variable, successive sampling, bias, mean square error, optimum replacement policy.

1. Introduction

The successive method of sampling consists in selecting samples of the same size on different occasions such that some units are common to samples selected on previous occasions. In successive sampling, the ratio estimator is among the most commonly adopted estimators of the population mean or total of some variables of interest of a finite population with the help of an auxiliary variable when the correlation coefficient between the two variables is positive. Patterson (1950) and Cochran (1977) suggested a number of estimation procedures on

E-mail: gitasree22@gmail.com.
sampling over two occasions. Rao and Graham (1964), Gupta (1979), Das (1982), Sen (1971) developed estimators for the population mean on the current occasion using information on two auxiliary variables available on the previous occasion. Sen (1972, 1973) extended his work for several auxiliary variates. Singh et al. (1991) and Singh and Singh (2001) used the auxiliary information on current occasion for estimating the current population mean in two occasion successive sampling. Singh (2003) extended their work for h-occasions successive sampling.

Utilizing the auxiliary information on both the occasions, Singh (2005), Singh and Priyanka (2006, 2007a, 2008) proposed varieties of chain-type ratio, difference and regression estimators for estimating the population mean on the current (second) occasion in two occasion successive sampling. Singh (2005) suggested two estimators for population mean using the information on an auxiliary variable in successive sampling over two occasions. Consider a character under study on the first (second) occasion is denoted by \(x(y)\) respectively and the auxiliary variable \(z\) is available on both the occasions. A simple random sample (without replacement) of \(n\) units is taken on the first occasion. The suggested chain-type ratio estimator based on the sample of size \(m\) \((= n\lambda)\) common to both the occasions is given by

\[
T_2 = \frac{\bar{y}_m \bar{x}_n \bar{Z}}{\bar{x}_m \bar{z}_n}
\]  

(1)

The bias \(B(.)\) and mean square error \(M(.)\) of \(T_2\) up to the first order of approximation and for large population of size \(N\) of equation (1) are derived as

\[
B(T_2) = \bar{Y} \left[ \left( \frac{1}{m} - \frac{1}{n} \right) \left( C_x^2 - 2\rho_{yx} C_y C_x \right) + \frac{1}{n} \left( C_z^2 - 2\rho_{yz} C_y C_z \right) \right]
\]

and

\[
M(T_2) = \bar{Y}^2 \left[ \frac{C_y^2}{m} + \left( \frac{1}{m} - \frac{1}{n} \right) \left( C_x^2 - 2\rho_{yx} C_y C_x \right) + \frac{1}{n} \left( C_z^2 - 2\rho_{yz} C_y C_z \right) \right]
\]

A classical ratio estimator based on a sample of size \(u = n - m = n\mu\) (fraction of a sample) drawn afresh on the second occasion is given by

\[
T_1 = \frac{\bar{y}_u \bar{Z}}{\bar{z}_u}
\]

(2)

Combining \(T_1\) and \(T_2\), the resulting estimator of \(\bar{Y}\) is

\[
T = \phi T_1 + (1 - \phi) T_2
\]

where \(\phi\) is an unknown constant to be determined under certain optimum criterion.

After optimizing \(\phi\) and \(\mu\) (sampling fraction), the optimum mean square error of the estimator \(T\) is given by
Following the chain-type ratio estimator proposed by Singh (2005), in the present work we propose a chain ratio-to-regression estimator for estimating population mean on the current occasion using auxiliary information that is available on both the occasions. The behaviour of the proposed estimator have been examined analytically and also through empirical means of comparison.

2. Proposed estimator

Consider a population consisting of N units. Let a character under study on the first (second) occasion be denoted by x(y), respectively. It is assumed that the information on an auxiliary variable z is available on the first as well as on the second occasion. We consider the population to be large enough, and the sample size is constant on each occasion. Using simple random sampling without replacement (SRSWOR) we select a sample of size n on the first occasion. Of these n units, a sub-sample of size $m = n\lambda$ is retained on the second occasion. This sub-sample is supplemented by selecting SRSWOR of $u = (n - m) = n(1 - \lambda)$ units afresh from the units that were not selected on the first occasion.

By modifying the estimator in (1), we propose a chain ratio-to-regression estimator for $\bar{Y}$ on the second occasion which is based on a sample of size m common to both the occasions and is given by

$$T_p = \frac{\bar{y}_m}{x_m} \left[ \bar{x}_m + b_{xz} (\bar{z}_n - \bar{z}_m) \right] \frac{\bar{Z}}{Z_n}$$

(3)

where

$\bar{Z}$ : Population mean of z.

$\bar{x}_m, \bar{y}_m, \bar{z}_m, \bar{z}_n$ : Sample means of the respective variates with sample sizes as shown in the subscript.

$b_{xz}$ : Regression coefficient of x on z.
The bias of the proposed estimator $T_p$ up to the second order of approximation as obtained in Appendix A is:

$$
\text{Bias}(T_p) = \frac{1}{X} \beta_{xz} \left( \beta_{xz} \mathbb{E}\left( z_n, s_{xz}^2 \right) + \mathbb{E}\left( z_n, s_{xz} \right) + \mathbb{E}\left( z_m, s_{xz}^2 \right) + \mathbb{E}\left( z_m, s_{xz} \right) \right)
$$

$$
+ \beta_{xz} \left[ \mathbb{E}(\bar{y}_m, z_n) - \mathbb{E}(\bar{x}_m, \bar{z}_m) \right] - \frac{\bar{Y}}{X} \operatorname{Var}(\bar{x}_m)
$$

$$
- \beta_{xz} \frac{\bar{Y}}{X} \left[ \mathbb{E}(\bar{x}_m, z_n) - \mathbb{E}(\bar{y}_m, \bar{z}_m) \right] - \bar{X} \mathbb{E}(\bar{y}_m, z_n) + \frac{\bar{X} \bar{Y}}{Z^2} \operatorname{Var}(\bar{z}_m)
$$

(4)

And the mean square error of $T_p$ considering $E(T_p)$ up to the first order of approximation obtained in Appendix B is:

$$
\mathbb{M}(T_p) = \bar{Y}^2 \left[ \frac{C_y^2}{m} + \left( \frac{1}{m} - \frac{1}{n} \right) \left( \rho_{xz}^2 C_x^2 - 2 \rho_{xz} \rho_{yz} C_x C_y \right) + \frac{1}{n} \left( C_z^2 - 2 \rho_{yz} C_y C_z \right) \right]
$$

(5)

Following Singh (2005), we combine the estimators $T_1$ and $T_p$ and the final estimator of $\bar{Y}$ on the second occasion is given as

$$
T_{p_i} = \psi T_1 + (1 - \psi) T_p
$$

(6)

where $\psi$ is an unknown constant to be determined under certain criterion.

3. Bias and mean square error of a combined estimator $T_{p_i}$

Since both $T_1$ and $T_p$ are biased estimators of $\bar{Y}$, therefore, the resulting estimator $T_{p_i}$ is also a biased estimator of $\bar{Y}$. Using the notations in Section 2, the bias $B(T_{p_i})$ and mean square error $M(T_{p_i})$ up to the first order of approximation are given below:

$$
B(T_{p_i}) = \psi B(T_1) + (1 - \psi) B(T_p)
$$

(7)

and

$$
M(T_{p_i}) = \psi^2 M(T_1) + (1 - \psi)^2 M(T_p)
$$

(8)
where, from Cochran (1977)

\[ B(T_i) = \frac{\bar{Y}}{u} \left( C_z - \rho_{yz} C_y C_z \right) \]  
(9)

and

\[ M(T_i) = \frac{\bar{Y}^2}{u} \left( C_y^2 + C_z^2 - 2\rho_{yz} C_y C_z \right) \]  
(10)

4. **Minimum mean square error of** \( T_{pi} \)

Since \( M(T_{pi}) \) in (8) is a function of unknown constant \( \psi \), therefore, it is minimized with respect to \( \psi \) and subsequently the optimum value of \( \psi \) obtained in Appendix C is

\[ \psi_{\text{opt}} = \frac{M(T_p)}{M(T_i) + M(T_p)} \]  
(11)

Now, substituting the value of \( \psi_{\text{opt}} \) in equation (8) we obtain the optimum mean square error of \( T_{pi} \) (given in Appendix C) as

\[ M(T_{pi})_{\text{opt}} = \frac{M(T_i)M(T_p)}{M(T_i) + M(T_p)} \]  
(12)

Using equation (5) and (10), let

\[ A' = \bar{Y}^2 C_y^2, \quad B' = \bar{Y}^2 \left( \rho_{xz}^2 C_x^2 - 2\rho_{xz}\rho_{yz} C_x C_y \right), \quad C' = \bar{Y}^2 \left( C_z^2 - 2\rho_{yz} C_y C_z \right) \]

Then, from Appendix C

\[ M(T_{pi})_{\text{opt}} = \frac{(A' + C')^2 + (A' + C')(B' - C')\mu}{n\left[ (A' + C') + (B' - C')\mu^2 \right]} \]

or

\[ M(T_{pi})_{\text{opt}} = \frac{(\alpha_1')^2 + \alpha_1'\alpha_2'\mu}{n[\alpha_1' + \alpha_2'\mu^2]} \]  
(13)

where \( \alpha_1' = A' + C' \), \( \alpha_2' = B' - C' \)
5. Optimum replacement policy

To determine the optimum value of $\mu$ (fraction of a sample to be taken afresh at the second occasion) so that population mean $\bar{Y}$ may be estimated with maximum precision, we minimize mean square error of $T_{pi}$ with respect to $\mu$ which results in quadratic equation in $\mu$ and solution of $\mu$ (from Appendix D) is given below:

$$
\mu_0 = -\alpha_1 \pm \sqrt{(\alpha_1')^2 + (\alpha_1' \alpha_2')} \over \alpha_2' 
$$

$$
= -2(1-\rho_{yz}) \pm \sqrt{2(1-\rho_{yz})\{2(1-\rho_{yz}) + (1-\rho_{xz})(2\rho_{yz} - \rho_{xz} - 1)\}} 
\over (1-\rho_{xz})(2\rho_{yz} - \rho_{xz} - 1) 
$$

From equation (14), it is obvious that the real value of $\mu_0$ exists if the quantities under square root are greater than or equal to zero. To choose the admissible value of $\mu_0$, it should be remembered that $0 \leq \mu_0 \leq 1$. All other values of $\mu_0$ are inadmissible. Substituting the value of $\mu_0$ from (14) in (13), we have

$$
M(T_{pi})_{opt} = \left( \frac{(\alpha_1')^2 + \alpha_1' \alpha_2' \mu_0}{n[\alpha_1' + \alpha_2' \mu_0]^2} \right) 
$$

6. Comparison of mean square error and efficiency

Now we compare the optimum MSE of the proposed estimator $T_{pi}$ with (i) the optimum MSE of the estimator proposed by Singh (2005), (ii) $\bar{y}_n$, i.e. mean per unit estimator, and (iii) $\bar{y}_2$ (Cochran, 1977) when no auxiliary information is used at any occasion. In each case, we obtain conditions under which the estimator $T_{pi}$ is better than the three estimators mentioned above.

(i) Comparison with Singh’s (2005) estimator.

First, we consider the estimator $T = (\phi)T_1 + (1-\phi)T_2$ which is due to Singh (2005). The variance of this estimator, to the first order of approximation and for large population, is given as

$$
M(T) = \frac{1}{n\mu(1-\mu)} \left[ \phi^2 \alpha_1 (1-\mu) + (1-\phi)^2 \left( \alpha_1 \mu + \alpha_2 \mu^2 \right) \right] 
$$
where
\[ \alpha_1 = A - C, \quad \alpha_2 = B - C, \quad A = \bar{Y}^2 C_y^2, \quad B = \bar{Y}^2 \left( C_x^2 - 2\rho_{yx} C_y C_x \right), \quad C = \bar{Y}^2 \left( C_z^2 - 2\rho_{yz} C_y C_z \right) \]

The variance of \( T \) is minimized for
\[ \phi_{\text{opt}} = \frac{\mu \left( \alpha_1 + \alpha_2 \mu \right)}{\left( \alpha_1 + \alpha_2 \mu^2 \right)} \]

Thus, the resulting minimum variance of \( T \) is
\[ M(T)_{\text{opt}} = \frac{\alpha_1^2 + \alpha_1 \alpha_2 \mu}{n \left[ \alpha_1 + \alpha_2 \mu^2 \right]} \]

Under the assumption of \( C_x = C_y = C_z = C \), minimizing \( M(T)_{\text{opt}} \) with respect to \( \mu \), the optimum value of \( \mu \) (fraction of a sample to be taken afresh at the second occasion) is given by
\[ \left[ -\alpha_1 \pm \sqrt{\alpha_1^2 + \alpha_1 \alpha_2} \right] = \frac{\left( 1 - \rho_{yz} \right) \pm \sqrt{\left( 1 - \rho_{yx} \right) \left( 1 - \rho_{yx} \right)}}{\rho_{yz} - \rho_{yx}} = \mu_0 \text{(say)} \]

Therefore,
\[ M(T)_{\text{opt}} = \frac{\alpha_1^2 + \alpha_1 \alpha_2 \mu_0}{n \left[ \alpha_1 + \alpha_2 \mu_0^2 \right]} \]

The proposed combined estimator \( T_{p_1} \) is better than the combined estimator proposed by Singh (2005) if
\[ M(T)_{\text{opt}} - M(T_{p_1})_{\text{opt}} > 0 \]
\[ \Rightarrow \frac{\alpha_1^2 + \alpha_1 \alpha_2 \mu_0}{n \left[ \alpha_1 + \alpha_2 \mu_0^2 \right]} - \frac{\left( \alpha_1 \right)^2 + \alpha_1 \alpha_2 \mu_0}{n \left[ \alpha_1 + \alpha_2 \left( \mu_0 \right)^2 \right]} > 0 \]
\[ \Rightarrow (1 - \rho)(1 - \mu_0) > 0 \]

(See Appendix E(i) for derivation of the above result)

Since \( 0 \leq \mu_0 \leq 1 \), \( (1 - \mu_0) \) is always positive and \( (1 - \rho) \) is always positive, which indicates that the above condition is always valid. That is, \( T_{p_1} \) is a better estimator than the estimator \( T \) proposed by Singh (2005).
(ii) Comparison with mean per unit estimator.

Next, we consider the mean per unit estimator $\bar{y}_n$ as follows:

$$\bar{y}_n = \frac{\sum_{i=1}^{n} y_i}{n},$$

under the assumption of $C_y = C$, the variance of mean per unit estimator is given by

$$V(\bar{y}_n) = \frac{\bar{Y}^2 C_y^2}{n} = \frac{\bar{Y}^2 C^2}{n}$$

The proposed combined estimator $T_{p_1}$ is better than this estimator if

$$V(\bar{y}_n) - M(T_{p_1})_{opt} > 0$$

$$\Rightarrow \left[ 2 - (1 - \rho)(\mu_0')^2 \right] > 2(1 - \rho)\left[ 2 - (1 - \rho)\mu_0 \right]$$

(16)

(See Appendix E(ii) for derivation of the above result)

Hence, $T_{p_1}$ is a better estimator than mean per unit estimator whenever equation (16) is satisfied. And it can be easily verified that the above condition is true for $\rho \geq 0.5$.

(iii) Comparison with Cochran’s (1977) estimator.

Now we consider the Cochran’s (1977) estimator $\bar{y}_2$ as follows:

$$\bar{y}_2 = \phi_2 \bar{y}_{2u} + (1 - \phi_2) \bar{y}_{2m},$$

i.e. combined estimator suggested by Cochran (1977) when no auxiliary information is used at any occasion.

Here, $\bar{y}_{2u}, \bar{y}_{2m}$ are the unmatched and matched portions of the sample at the second occasion respectively, and

$$\phi_2 = \frac{W_{2u}}{W_{2u} + W_{2m}}$$

where $W_{2u}$ and $W_{2m}$ are the inverse variances, i.e.

$$\frac{1}{W_{2u}} = V(\bar{y}_{2u}) = \frac{C_y^2 \bar{Y}^2}{u}, \quad \frac{1}{W_{2m}} = V(\bar{y}_{2m}) = \frac{C_y^2 \bar{Y}^2 (1 - \rho_{yx}^2)}{m} + \rho_{yx}^2 \frac{C_y^2 \bar{Y}^2}{n}$$
By least square theory, the variance of \( \bar{y}_2 \) is

\[
V(\bar{y}_2) = \frac{1}{W_{2u} + W_{2m}}
\]

\[
= \frac{C_y \bar{Y}^2 (n - u \rho_{yx})}{n^2 - u^2 \rho_{yx}^2}
\]

Minimizing \( V(\bar{y}_2) \) with respect to \( u \), the optimum value of \( u \) is given by

\[
u_{opt} = \frac{n}{1 + \sqrt{1 - \rho_{yx}^2}} \quad \text{and} \quad m_{opt} = \frac{n \left( \sqrt{1 - \rho_{yx}^2} \right)}{1 + \sqrt{1 - \rho_{yx}^2}}
\]

Under the assumption of \( C_y = C \), the optimum variance of the above estimator is given as

\[
V(\bar{y}_2)_{opt} = \left[ 1 + \sqrt{1 - \rho_{yx}^2} \right] \frac{\bar{Y}^2 C^2}{2n}
\]

Then, the proposed combined estimator \( T_{p_t} \) is better than this estimator if

\[
V(\bar{y}_2)_{opt} - M(T_{p_t})_{opt} > 0
\]

\[
\Rightarrow \left( 1 + \sqrt{1 - \rho^2} \right) \left[ 2 - (1 - \rho)(\mu_0^{'})^2 \right] > 4(1 - \rho)\left[ 2 - (1 - \rho)\mu_0^{' \prime} \right]
\]

(17)

(See Appendix E(iii) for derivation of the above result)

Hence, \( T_{p_t} \) is a better estimator than Cochran’s (1977) estimator whenever equation (17) is satisfied. And it can be easily verified that the above condition is true for \( \rho \geq 0.5 \).

Further, conditions (16) and (17) are true for all values of \( \rho \geq 0.5 \). This is justified since \( \rho_{yx} \) expresses the relationship between current occasion and previous occasion study variable, \( \rho_{xz} \) for previous occasion study variable and auxiliary variable and \( \rho_{yz} \) for current occasion study variable and auxiliary variable.

As an example, the percent relative efficiency of the proposed estimator \( T_{p_t} \) with respect to (i) \( T \), the estimator proposed by Singh (2005), (ii) \( \bar{y}_n \), i.e. mean per
unit estimator, and (iii) $\bar{y}_2$ (Cochran, 1977) when no auxiliary information is used on any occasion, have been computed for some assumed values of $\rho_{yx}, \rho_{yz}$ and $\rho_{zx}$. Since $\bar{y}_n$ and $\bar{y}_2$ are unbiased estimators of $\bar{Y}$, their variances for large N are respectively given by

$$V(\bar{y}_n) = \frac{\bar{Y}^2 C_y^2}{n}$$

and

$$V(\bar{y}_2)_{opt} = \left[1 + \sqrt{1 - \rho_{xy}^2}\right] \frac{\bar{Y}^2 C_y^2}{2n}$$

Here, $E_1$, $E_2$, $E_3$ are designated as the percent relative efficiencies of the proposed estimator $T_{p_1}$ with respect to Singh’s (2005) estimator $T$, $\bar{y}_n$ and $\bar{y}_2$, respectively.

Further, the expression of the optimum $\mu$, i.e. $\mu_0$ and the percent relative efficiencies $E_1$, $E_2$ and $E_3$ are in terms of population correlation coefficients. We assumed that all the correlations involved in the expressions of $\mu$, $E_1$, $E_2$ and $E_3$ are equal, i.e. $\rho_{xy} = \rho_{xz} = \rho_{yz} = \rho$. Accordingly, computed values of $\mu_0$, $E_1$, $E_2$ and $E_3$ for different choices of high positive correlations are shown in Table 1.

</tbody>
</table>

From Table 1, it is clear that the proposed estimator is more efficient than $T$, $\bar{y}_n$ and $\bar{y}_2$. Also, when the correlation coefficient $\rho \geq 0.5$ is increasing, the gain in precision of the proposed estimator $T_{p_1}$ over $T$, $\bar{y}_n$ and $\bar{y}_2$ is also increasing. Further, it may be noticed that the maximum gain in efficiency occurs while comparing it with mean per unit estimator, which is very obvious.
7. Illustration using real life data

In order to illustrate the comparison of relative efficiency of the proposed estimator with respect to (i) $T$, the estimator proposed by Singh (2005), (ii) $\bar{y}_n$, i.e. mean per unit estimator, and (iii) $\bar{y}_2$ (Cochran, 1977) when no auxiliary information is used on any occasion, using real life approach, the data from the Census of India (2001) and (2011) was considered. We define the variables $x(y)$ as the total number of workers in villages in the state of Mizoram, India in 2001 (2011) and $z$ is defined as an auxiliary variable which is the total number of literate people in villages in the state of Mizoram, India.

Using successive sampling as defined in section 2 for the above data set we take $n = 70$, $m = 35$ and $u = 35$. The following table shows the values of the different estimators as computed from the sample along with their corresponding mean square errors and efficiency of the proposed estimator $T_{pl}$ with respect to $T$, $\bar{y}_n$ and $\bar{y}_2$.

<table>
<thead>
<tr>
<th>Estimators</th>
<th>Estimates</th>
<th>MSE</th>
<th>Efficiency %</th>
</tr>
</thead>
<tbody>
<tr>
<td>$T_{pl}$</td>
<td>354</td>
<td>249.98</td>
<td>100</td>
</tr>

</tr>
<tr>
<td>$\bar{y}_2$</td>
<td>332</td>
<td>1240.26</td>
<td>496.14</td>
</tr>
</tbody>
</table>

The above table shows that the conclusions are the same as those of Table 1, that is the proposed estimator $T_{pl}$ is more efficient than $T$, $\bar{y}_n$ and $\bar{y}_2$ with maximum gain in efficiency occurring while comparing it with mean per unit estimator, which is very obvious.

8. Conclusion

In this study we have proposed a new chain ratio-to-regression estimator in successive sampling. The bias of the proposed estimator was computed up to the second order of approximation. The optimum replacement policy of the sampling fraction was obtained and considering bias up to the first order of approximation, the optimum mean square error of the proposed estimator was also obtained. The optimum mean square error of the proposed estimator was compared with that of
Singh’s (2005) estimator and it was found that the proposed estimator is always better than Singh’s (2005) estimator. Further, the proposed estimator was compared with mean per unit estimator and Cochran’s (1977) estimator when no auxiliary information is used on any occasion. It was found that the proposed estimator is better than both of these estimators for $0.5 \leq \rho$, which is entirely justified. An example was considered by assuming different values of $\rho \geq 0.5$ to illustrate the above facts. At the end, a real life study was also done to demonstrate that the proposed estimator is more efficient than the other three existing estimators. Hence, the proposed estimator is recommended for further use.

T_p = \left( \frac{\bar{Y} + \epsilon_0}{X + \epsilon_2} \right) \left[ \frac{X + \epsilon_2 + \left( \frac{S_{xz} + \epsilon_3}{S_z^2 + \epsilon_4} \right) (\bar{Z} + \epsilon_1 - \bar{Z})}{Z + \epsilon_1} \right] \left( \frac{\bar{Z}}{Z + \epsilon_1} \right)
\]

\[
= \frac{1}{X} \left( \frac{\bar{Y} + \epsilon_0}{X + \epsilon_2} \right) \left[ \frac{1 - \frac{\epsilon_2}{X} + \left( \frac{\epsilon_2}{X} \right)^2}{X + \epsilon_2 + \left( \frac{\epsilon_3}{S_z^2 + \epsilon_4} \right) \beta_{xz} (\epsilon_1 - \epsilon_1)} \right] \left[ 1 - \frac{\epsilon_1}{Z} + \frac{\epsilon_1^2}{Z^2} \right]
\]

\[
= \left\{ \frac{1}{X} \left( \frac{\bar{Y} + \epsilon_0 - \frac{\bar{Y}}{X} \epsilon_2 - \frac{\bar{Y}}{X} \epsilon_1 + \frac{\bar{Y}}{X} \epsilon_0 \epsilon_2 + \frac{\bar{Y}}{X} \epsilon_0 \epsilon_0}{\epsilon_0} - \frac{\bar{Y}}{X} \epsilon_0 \epsilon_1 + \frac{\bar{Y}}{X} \epsilon_0 \epsilon_2 + \frac{\bar{Y}}{X} \epsilon_0 \epsilon_0 \right) \right\}
\]

\[
\times \left\{ \frac{X + \epsilon_2 + \beta_{xz} \left( \frac{\epsilon_1}{S_z^2 + \epsilon_4} + \frac{\epsilon_1 \epsilon_3}{S_{xz}} \right) + \frac{\epsilon_1 \epsilon_4}{S_z^2} + \frac{\epsilon_1 \epsilon_3}{S_{xz}} \right\} \right]\}

\[
= \left\{ \frac{1}{X} \left( \frac{\bar{Y} X + \beta_{xz} \bar{Y} \left( -\frac{\epsilon_1 \epsilon_4}{S_z^2} + \frac{\epsilon_1 \epsilon_3}{S_{xz}} \right) + \beta_{xz} \left( \epsilon_0 \epsilon_1 - \epsilon_0 \epsilon_1 \right) \right)}{\bar{Y} X - \frac{\beta_{xz} \left( \epsilon_2 \epsilon_1 \epsilon_2 \right) - \beta_{xz} \left( \epsilon_1^2 - \epsilon_1 \epsilon_1 \right) - \bar{X} \epsilon_0 \epsilon_1 + \bar{X} \epsilon_1^2}{Z^2} \right\}
\]
Therefore,

\[
\begin{align*}
E(T_p) &= \bar{Y} + \frac{1}{X} \left\{ \beta_{xz} \left[ \text{Cov}(\bar{y}_m, \bar{z}_n) - \text{Cov}(\bar{y}_m, \bar{z}_m) \right] - \frac{\bar{Y}}{X} \text{Var}(\bar{x}_m) \right. \\
&\quad \left. - \beta_{xz} \frac{\bar{Y}}{X} \left[ \text{Cov}(\bar{x}_m, \bar{z}_n) - \text{Cov}(\bar{x}_m, \bar{z}_m) \right] - \bar{X} \text{Cov}(\bar{y}_m, \bar{z}_n) + \frac{\bar{X} \bar{Y}}{Z^2} \text{Var}(\bar{z}_n) \right\} \\
&= \beta_{xz} \bar{Y} \left( -\frac{\text{Cov}(\bar{z}_n, S^2_z)}{S_z^2} + \frac{\text{Cov}(\bar{z}_n, S_{xz})}{S_{xz}} + \frac{\text{Cov}(\bar{z}_m, S^2_z)}{S_z^2} + \frac{\text{Cov}(\bar{z}_m, S_{xz})}{S_{xz}} \right)
\end{align*}
\]

Hence, \( \text{Bias}(T_p) = E(T_p) - \bar{Y} \)

\[
\begin{align*}
&= \frac{1}{X} \left\{ \beta_{xz} \bar{Y} \left[ -\frac{\text{Cov}(\bar{z}_n, S^2_z)}{S_z^2} + \frac{\text{Cov}(\bar{z}_n, S_{xz})}{S_{xz}} + \frac{\text{Cov}(\bar{z}_m, S^2_z)}{S_z^2} + \frac{\text{Cov}(\bar{z}_m, S_{xz})}{S_{xz}} \right] \\
&\quad \frac{\bar{Y}}{X} \text{Var}(\bar{x}_m) - \beta_{xz} \frac{\bar{Y}}{X} \left[ -\frac{\text{Cov}(\bar{x}_m, S^2_z)}{S_z^2} + \frac{\text{Cov}(\bar{x}_m, S_{xz})}{S_{xz}} \right] - \bar{X} \text{Cov}(\bar{y}_m, \bar{z}_n) + \frac{\bar{X} \bar{Y}}{Z^2} \text{Var}(\bar{z}_n) \right\}
\end{align*}
\]

Appendix B

Mean Square Error of the proposed estimator

\( T_p = \frac{\bar{y}_m}{x_m} \left[ x_m + b_{xz} (\bar{z}_n - \bar{z}_m) \right] = \frac{\bar{z}_n}{z_n} \)

From (18), we can see that up to the first order of approximation \( E(T_p) = \bar{Y} \).

Therefore, mean square error up to the first order of approximation is given by \( M(T_p) = E(T_p)^2 - \bar{Y}^2 \).

Now,

\[
T_p = \left[ \frac{\bar{y}_m + \epsilon_1}{x_m + \epsilon_2} \right] \left[ \frac{\bar{X} + \epsilon_3 + S_{xz} + \epsilon_4}{S^2_z + \epsilon_3} \right] \left( \bar{Z} + \epsilon_5 - \bar{Z} - \epsilon_1 \right) \left( \frac{\bar{Z}}{Z + \epsilon_1} \right)
\]
\[
\left( T_p \right)^2 = \frac{1}{X^2} \left( Y + \frac{\epsilon_0 \cdot Y}{X} \right) \left( X + \epsilon_2 + \left( 1 + \frac{\epsilon_3}{S_{xz}} \right) \left( 1 + \frac{\epsilon_4}{S_z} \right) \beta_{xz} \left( \epsilon_1 - \epsilon_1 \right) \right) \left( 1 - \frac{\epsilon_1}{Z} \right)
\]

Therefore,
\[
\left( T_p \right)^2 = \frac{1}{X^2} \left( Y + \frac{\epsilon_0 \cdot Y}{X} \right) \left( X + \epsilon_2 + \left( 1 + \frac{\epsilon_3}{S_{xz}} \right) \left( 1 + \frac{\epsilon_4}{S_z} \right) \beta_{xz} \left( \epsilon_1 - \epsilon_1 \right) \right) \left( 1 - \frac{\epsilon_1}{Z} \right)
\]

Now again,
\[
E \left( T_p \right)^2 = \frac{1}{X^2} E \left( \frac{XY + X\epsilon_0 + \beta_{xz} \overline{Y} \epsilon_1 - \beta_{xz} \overline{Y} \epsilon_1 \cdot \frac{\overline{XY}}{Z} \epsilon_i}{\epsilon_i} \right)
\]

Assuming the terms up to the second order of approximation and neglecting terms higher than 2\(^{nd}\) power of \(\epsilon\)'s, we have
\[
E \left( T_p \right)^2 = \frac{1}{X^2} \left( \frac{(XY)^2 + X^2 (\epsilon_0)^2 + \beta_{xz} Y^2 (\epsilon_1)^2 + \left( \frac{XY}{Z} \right)^2 \epsilon_i^2 + 2\beta_{xz} \overline{XY} \epsilon_0 \epsilon_i}{\epsilon_i} \right)
\]

\[
= \overline{Y}^2 \left[ 1 + \frac{C_y}{m} + \frac{1}{m} \left( \frac{1}{n} \right) \left( \frac{\rho_{xz} C_x^2 - 2\rho_{xz} \rho_{yz} C_x C_y}{n} \right) \left( \frac{1}{n} \right) \left( C_z^2 - 2\rho_{yz} C_y C_z \right) \right]
\]

Therefore,
\[
M(T_p) = E(T_p)^2 - \overline{Y}^2 = \overline{Y}^2 \left[ 1 + \frac{C_y}{m} + \frac{1}{m} \left( \frac{1}{n} \right) \left( \frac{\rho_{xz} C_x^2 - 2\rho_{xz} \rho_{yz} C_x C_y}{n} \right) \left( \frac{1}{n} \right) \left( C_z^2 - 2\rho_{yz} C_y C_z \right) \right]
\]

Appendix C

Minimum Mean Square Error of \( T_p \)

From equation (8), we have
\[
M(T_p) = \psi^2 M(T_i) + (1 - \psi)^2 M(T_p)
\]

(19)
Since $M(T_p)$ is a function of an unknown constant $\psi$, therefore, it is minimized with respect to $\psi$, i.e. differentiating $M(T_p)$ with respect to $\psi$ and equating them to zero, we get

$$\Rightarrow \psi_{opt} = \frac{M(T_p)}{M(T_1) + M(T_p)}$$

Then, substituting $\psi_{opt}$ from equation (19), the minimum MSE of $T_{p_1}$ as

$$M(T_{p_1})_{opt} = \frac{M(T_1)M(T_p)}{[M(T_1) + M(T_p)]}$$

For simplification, let

$$A' = \overline{Y}^2 C_y^2, \quad B' = \overline{Y}^2 (\rho_{xz}^2 C_x^2 - 2\rho_{xz} \rho_{yz} C_x C_y), \quad C' = \overline{Y}^2 (C_z^2 - 2\rho_{yz} C_y C_z)$$

Therefore,

$$M(T_1) = \frac{A' + C'}{u} = \frac{A' + C'}{n\mu}$$

$$M(T_p) = \frac{A'}{m} + \left( A' \frac{1}{m} - C' \frac{1}{n} \right) B' + C' = \frac{A'}{m} + \frac{B'\mu}{n(1-\mu)} + \frac{C'}{n} \text{ since } m=n-u=n-\mu=n(1-\mu)$$

Now,

$$M(T_{p_1})_{opt} = \frac{n}{(A' + C')(1-\mu) + A'\mu + B'\mu^2 + C'\mu (1-\mu)}$$

$$= \frac{(A' + C')^2 + (A' + C')(B' - C')\mu}{n[(A' + C') + (B' - C')\mu^2]}$$

or

$$M(T_{p_1})_{opt} = \frac{(\alpha_1')^2 + \alpha_1' \alpha_2' \mu}{n[\alpha_1' + \alpha_2' \mu^2]} \tag{20}$$

where

$$\alpha_1' = A' + C', \quad \alpha_2' = B' - C'$$
Appendix D
Optimum Replacement Policy
Differentiating $M(T_{pi})_{opt}$ from equation (20) with respect to $\mu$ and equating them to zero, we get

$$\frac{1}{n} \left[ \left( \alpha_i' + \alpha_2' \mu^2 \right) \left( \alpha_i' \alpha_2' \right) - \left( \left( \alpha_i' \right)^2 + \alpha_i' \alpha_2' \mu \right) \left( 2 \alpha_2' \mu \right) \right] \left( \alpha_i' + \alpha_2' \mu^2 \right)^2 = 0$$

$$\Rightarrow \left( \alpha_i' \alpha_2' \right) \mu^2 + 2 \left( \alpha_i' \alpha_2' \right) \mu - \left( \alpha_i' \right)^2 = 0$$

Then, $\mu = \left[ -\alpha_i' \pm \sqrt{\left( \alpha_i' \right)^2 + \left( \alpha_i' \alpha_2' \right)} \right] / \alpha_2'$

Now, assuming $C_x = C_y = C_z = C$ (say)

$$\alpha_i' = A' + C' = \bar{Y}^2 C_y^2 + \bar{Y}^2 \left( C_z^2 - 2 \rho_{yz} C_y C_z \right)$$

$$= 2 \bar{Y}^2 C^2 \left( 1 - \rho_{yz} \right)$$

$$\alpha_2' = B' - C' = \bar{Y}^2 \left[ \rho_{xz} C_x^2 - 2 \rho_{xz} \rho_{yz} C_x C_y \right] - \bar{Y}^2 \left( C_z^2 - 2 \rho_{yz} C_y C_z \right)$$

$$= \bar{Y}^2 C^2 \left[ \left( 1 - \rho_{xz} \right) \left( 2 \rho_{xz} - 1 - \rho_{xz} \right) \right]$$

$$\alpha_i' \alpha_2' = \left( A' + C' \right) \left( B' - C' \right)$$

$$= 2 \bar{Y}^2 C^2 \left( 1 - \rho_{yz} \right) \left[ \bar{Y}^2 C^2 \left[ \left( 1 - \rho_{xz} \right) \left( 2 \rho_{yz} - 1 - \rho_{xz} \right) \right] \right]$$

$$= \left( \bar{Y}^2 C \right)^2 \left[ 2 \left( 1 - \rho_{yz} \right) \left( 1 - \rho_{xz} \right) \left( 2 \rho_{yz} - 1 - \rho_{xz} \right) \right]$$

Therefore, $\mu = \left[ -\alpha_i' \pm \sqrt{\left( \alpha_i' \right)^2 + \left( \alpha_i' \alpha_2' \right)} \right] / \alpha_2'$

$$= \frac{-2 \left( 1 - \rho_{yz} \right) \pm \sqrt{2 \left( 1 - \rho_{yz} \right) \left( 2 \left( 1 - \rho_{yz} \right) + \left( 1 - \rho_{xz} \right) \left( 2 \rho_{yz} - \rho_{xz} - 1 \right) \right)}} {\left( 1 - \rho_{xz} \right) \left( 2 \rho_{yz} - \rho_{xz} \right) - 1} = \mu_0' \text{ (say)}$$
Appendix E

Comparison of mean square error

(i). $M(T_{opt}) - M(T_{p_1})_{opt} > 0$

$$\Rightarrow \frac{\alpha_1^2 + \alpha_2 \mu_0}{n[\alpha_1^2 + \alpha_2 \mu_0^2]} - \frac{(\alpha_1^2 + \alpha_2 \mu_0^2)^2}{n[\alpha_1^2 + \alpha_2 (\mu_0^2)]^2} > 0$$

$$\Rightarrow \left[\frac{1-\rho_{yz} + (\rho_{yz} - \rho_{xz}) \mu_0}{2} \right] - \left[\frac{2(1-\rho_{yz} + (1-\rho_{xz})(2\rho_{yz} - 1-\rho_{xz}) \mu_0^2}{2} \right] > 0$$

(21)

Let us assume that $\rho_{xz} = \rho_{yz} = \rho$ (say), equation (21) will become

$$\Rightarrow 1 - \frac{2(1-\rho) \mu_0^2}{2-1-\rho \mu_0^2} > 0$$

Therefore,

$M(T_{opt}) - M(T_{p_1})_{opt} > 0 \Rightarrow (1-\rho)(1-\mu_0^2) > 0$

(ii). $V(\bar{y}_n) - M(T_{p_1})_{opt} > 0$

$$\Rightarrow \left\{1 - \frac{2(1-\rho_{yz}) \left[2(1-\rho_{yz} + (1-\rho_{xz})(2\rho_{yz} - 1-\rho_{xz}) \mu_0^2\right]}{2(1-\rho_{yz} + (1-\rho_{xz})(2\rho_{yz} - 1-\rho_{xz}) \mu_0^2\right]} > 0 \right\}$$

Assuming that $\rho_{xz} = \rho_{yz} = \rho$ (say), equation (22) will become

$$1 - \frac{2(1-\rho)[2-(1-\rho) \mu_0^2]}{2-(1-\rho) \mu_0^2} > 0$$

$$\Rightarrow \left[2-(1-\rho) \mu_0^2\right] - 2(1-\rho) \left[2-(1-\rho) \mu_0^2\right] > 0$$
Therefore,

\[
V(\bar{y}_n) - M(T_{p_1})_{\text{opt}} > 0
\]

\[
\Rightarrow \left[2 - (1-p)(\mu_0)^2 + 2(1-p)(1-\rho)\right] > 0
\]

(iii). \(V(\bar{y}_2)_{\text{opt}} - M(T_{p_1})_{\text{opt}} > 0\)

\[
\Rightarrow \left[1 + \sqrt{1-\rho_{xy}^2}\right] \frac{\bar{Y}^2 C^2}{2n} - \frac{2\left(\frac{\bar{Y}^2 C^2}{n}\right)^2 \left[2(1-\rho_{yz})+ (1-\rho_{xz})(2\rho_{yz} - 1-\rho_{xz})(\mu_0)^2\right]}{2(1-\rho_{yz}) + (1-\rho_{xz})(2\rho_{yz} - 1-\rho_{xz})(\mu_0)^2} > 0
\]

(23)

Assuming \(\rho_{xz} = \rho_{yz} = \rho\) (say), equation (23) will become

\[
\Rightarrow \left(1 + \sqrt{1-\rho^2}\right) \left[2 - (1-p)(\mu_0)^2\right] - 4(1-p)(1-\rho) > 0
\]

Therefore,

\[
V(\bar{y}_2)_{\text{opt}} - M(T_{p_1})_{\text{opt}} > 0
\]

\[
\Rightarrow \left(1 + \sqrt{1-\rho^2}\right) \left[2 - (1-p)(\mu_0)^2\right] > 4(1-p)(1-\rho)
\]
